Libraries

Risk Management: European Options Portfolio

The objective is to implement (part of) the risk management framework for estimating the risk of a book of European call options by taking into account the risk drivers such as underlying and implied volatility.

Data

Load the database Market. Identify the price of the **SP500**, the **VIX index**, the term structure of interest rates (current and past), and the traded options (calls and puts).

```
# load dataset into environment
load(file = here("data_raw", "Market.rda"))

# reassign name and inspect structure of loaded data
mkt <- Market
summary(mkt)
```

```
##       Length Class  Mode
## sp500 3410   xts    numeric
## vix   3410   xts    numeric
## rf      14   -none- numeric
## calls 1266   -none- numeric
## puts  2250   -none- numeric
```

```
str(mkt)
```

```
## List of 5
##  $ sp500:An xts object on 2000-01-03 / 2013-09-10 containing:
##   Data:    double [3410, 1]
##   Index:   Date [3410] (TZ: "UTC")
##  $ vix  :An xts object on 2000-01-03 / 2013-09-10 containing:
##   Data:    double [3410, 1]
##   Index:   Date [3410] (TZ: "UTC")
##  $ rf   : num [1:14, 1] 0.00071 0.00098 0.00128 0.00224 0.00342 ...
##   ..- attr(*, "names")= chr [1:14] "0.00273972602739726" "0.0192307692307692" "0.0833333333333333" "0.25" .
##  $ calls: num [1:422, 1:3] 1280 1370 1380 1400 1415 ...
##   ..- attr(*, "dimnames")=List of 2
##   .. ..$ : NULL
##   .. ..$ : chr [1:3] "K" "tau" "IV"
##  $ puts : num [1:750, 1:3] 1000 1025 1050 1075 1100 ...
##   ..- attr(*, "dimnames")=List of 2
##   .. ..$ : NULL
##   .. ..$ : chr [1:3] "K" "tau" "IV"
```

Let's unpack these into the env. individually:

```
# unpack each of the elements in the mkt list
sp500 <- mkt$sp500
vix <- mkt$vix
Rf <- mkt$rf # risk-free rates
calls <- mkt$calls
puts <- mkt$puts

# assign colname for aesthetic
colnames(sp500) <- "sp500"
colnames(vix) <- "vix"
```

SP500 and VIX

By inspection, we observe that we the SP500 and VIX indices are contained in the `sp500` and `vix` xts objects respectively.

```
# show head of both indexes
head(sp500)
```

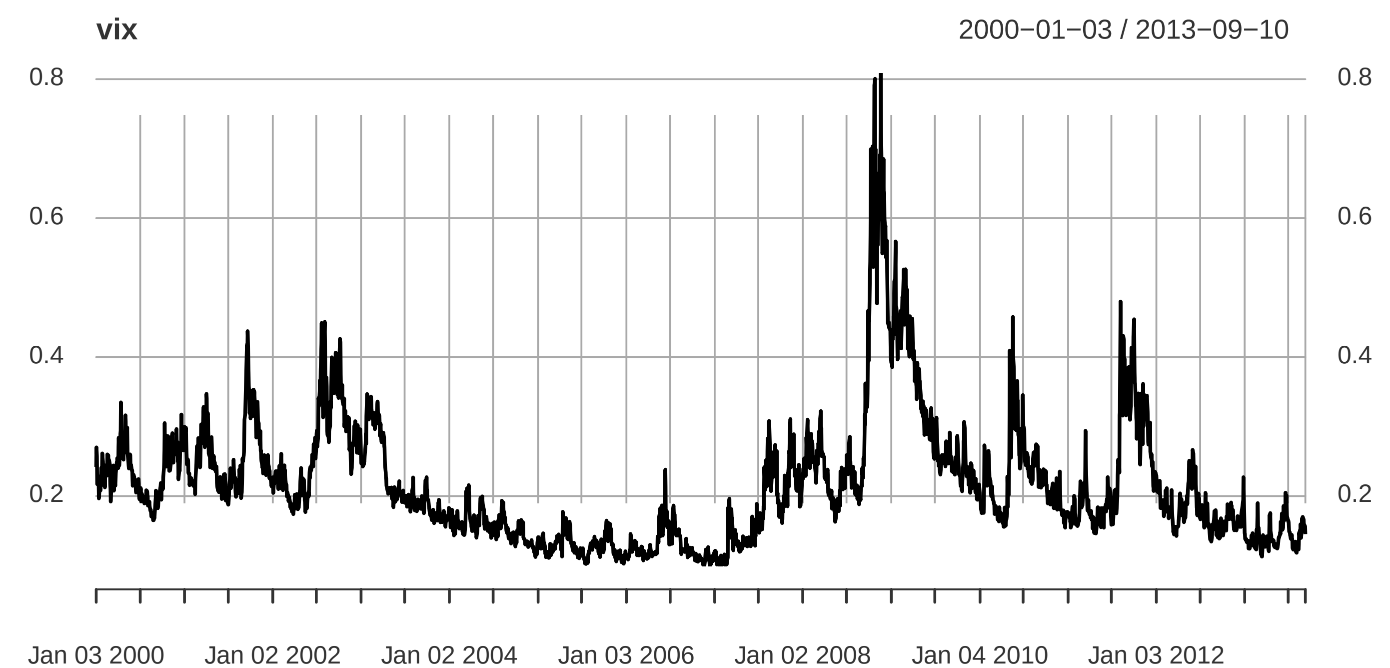
```
##               sp500
## 2000-01-03 1455.22
## 2000-01-04 1399.42
## 2000-01-05 1402.11
## 2000-01-06 1403.45
## 2000-01-07 1441.47
## 2000-01-10 1457.60
```

```
head(vix)
```

```
##                vix
## 2000-01-03 0.2421
## 2000-01-04 0.2701
## 2000-01-05 0.2641
## 2000-01-06 0.2573
## 2000-01-07 0.2172
## 2000-01-10 0.2171
```

```
par(mfrow = c(2,1))

# plot both series on top of each other
plot(sp500)
plot(vix)
```



Interest Rates

The **interest rates** are given in the `$rf` attribute. We can see that

```
Rf
```

```
##              [,1]
##  [1,] 0.0007099993
##  [2,] 0.0009799908
##  [3,] 0.0012799317
##  [4,] 0.0022393730
##  [5,] 0.0034170792
##  [6,] 0.0045123559
##  [7,] 0.0043206525
```

```
##   [8,] 0.0064284968
##   [9,] 0.0090558654
##  [10,] 0.0117237591
##  [11,] 0.0141196498
##  [12,] 0.0176131823
##  [13,] 0.0207989304
##  [14,] 0.0203526819
## attr(,"names")
##   [1] "0.00273972602739726" "0.0192307692307692"  "0.0833333333333333"
##   [4] "0.25"                "0.5"                 "0.75"
##   [7] "1"                   "2"                   "3"
##  [10] "4"                   "5"                   "7"
##  [13] "10"                  "30"
```

These represent the interest rates at different maturities. The maturities are given as follows:

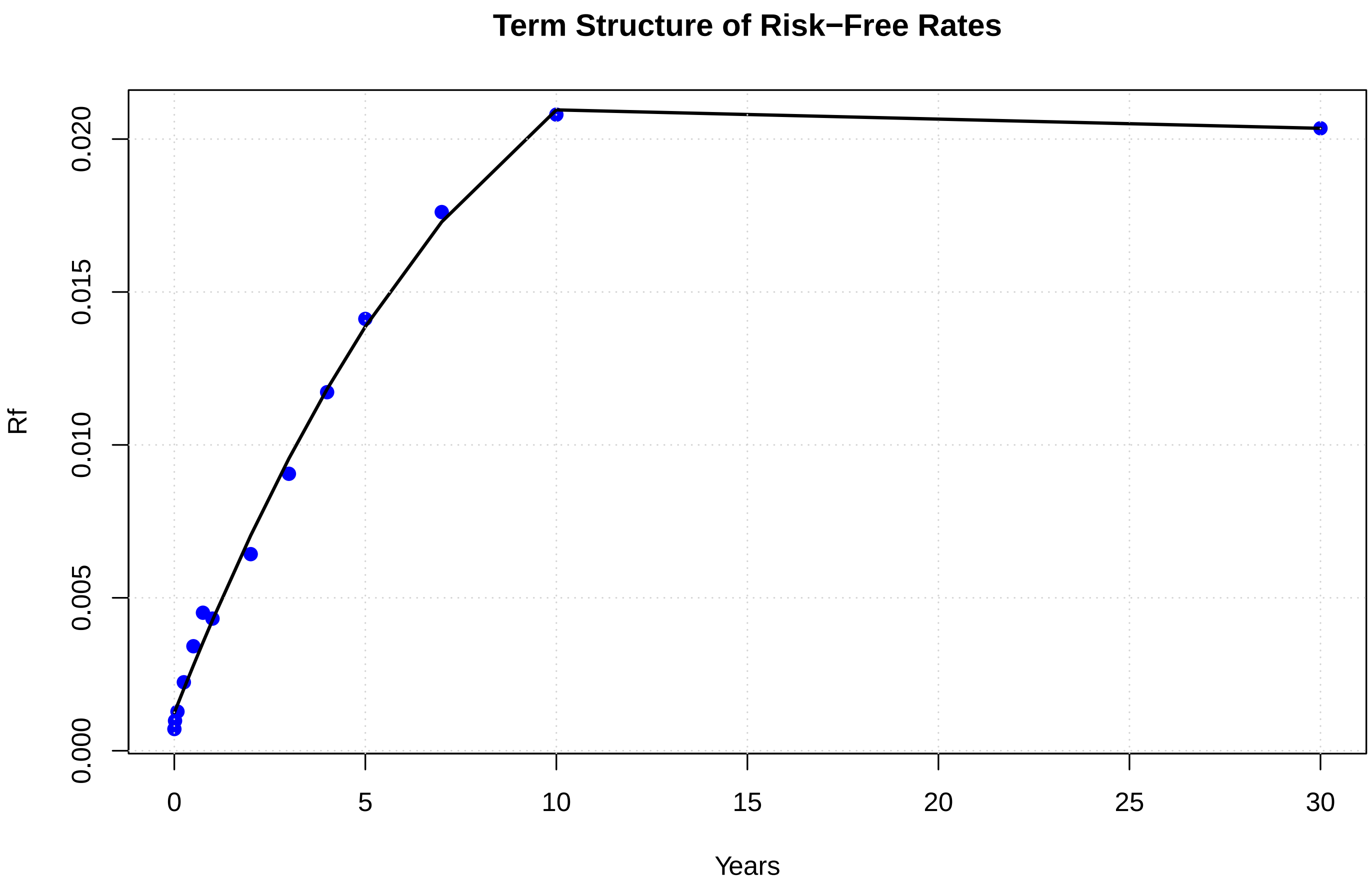
```
r_f <- as.vector(Rf)
names(r_f) <- c("1d","1w", "1m", "3m", "6m", "9m", "1y", "2y", "3y", "4y", "5y", "7y","10y", "30y")
r_f
```

```
##           1d           1w           1m           3m           6m           9m
## 0.0007099993 0.0009799908 0.0012799317 0.0022393730 0.0034170792 0.0045123559
##           1y           2y           3y           4y           5y           7y
## 0.0043206525 0.0064284968 0.0090558654 0.0117237591 0.0141196498 0.0176131823
##          10y          30y
## 0.0207989304 0.0203526819
```

Further, we can pack different sources of information in a matrix:

```
# pack Rf into a matrix with rf, years, and days
rf_mat <- as.matrix(r_f)
rf_mat <- cbind(rf_mat, as.numeric(names(Rf)))
rf_mat <- cbind(rf_mat, rf_mat[, 2]*360)
colnames(rf_mat) <- c("rf", "years", "days")
rf_mat
```

```
##                rf       years          days
## 1d  0.0007099993  0.002739726     0.9863014
## 1w  0.0009799908  0.019230769     6.9230769
## 1m  0.0012799317  0.083333333    30.0000000
## 3m  0.0022393730  0.250000000    90.0000000
## 6m  0.0034170792  0.500000000   180.0000000
## 9m  0.0045123559  0.750000000   270.0000000
## 1y  0.0043206525  1.000000000   360.0000000
## 2y  0.0064284968  2.000000000   720.0000000
## 3y  0.0090558654  3.000000000  1080.0000000
## 4y  0.0117237591  4.000000000  1440.0000000
## 5y  0.0141196498  5.000000000  1800.0000000
## 7y  0.0176131823  7.000000000  2520.0000000
## 10y 0.0207989304 10.000000000  3600.0000000
## 30y 0.0203526819 30.000000000 10800.0000000
```



Calls

The `calls` object displays the different values of K (**Strike Price**), τ (**time to maturity**) and $\sigma = IV$ (**Implied Volatilty**)

```
dim(calls)
```

```
## [1] 422   3
```

```
head(calls)
```

```
##         K        tau        IV
## [1,] 1280 0.02557005 0.7370370
## [2,] 1370 0.02557005 0.9691616
## [3,] 1380 0.02557005 0.9451401
## [4,] 1400 0.02557005 0.5274481
## [5,] 1415 0.02557005 0.5083375
## [6,] 1425 0.02557005 0.4820041
```

Add `days` column for convenience:

```
calls <- cbind(calls, calls[, "tau"]*250)
colnames(calls) <- c("K","tau", "IV", "tau_days")
head(calls)
```

```
##         K        tau        IV tau_days
## [1,] 1280 0.02557005 0.7370370 6.392513
## [2,] 1370 0.02557005 0.9691616 6.392513
## [3,] 1380 0.02557005 0.9451401 6.392513
```

```
## [4,] 1400 0.02557005 0.5274481 6.392513
## [5,] 1415 0.02557005 0.5083375 6.392513
## [6,] 1425 0.02557005 0.4820041 6.392513
```

```
tail(calls)
```

```
##           K      tau        IV tau_days
## [417,] 1925 2.269406 0.1605208 567.3514

```

Pricing a Portfolio of Options

Black-Scholes

Notation:

- S_t = Current value of underlying asset price
- K = Options **strike price**
- T = Option **maturity** (in years)
- t = **time** in years
- $\tau = T - t$ = **Time to maturity**
- r = **Risk-free rate**
- y **Dividend yield**
- $R = r - y$
- σ = **Implied volatility**
- c = **Price Call Option**
- p = **Price Put Option**

Proposition 1 (Black-Scholes Model)**.** Assume the notation before, and let $N(\cdot)$ be the cumulative standard normal distribution function. Under certain assumptions, the Black-Scholes models prices Call and Put options as follows:

$$\begin{cases} C(S_t, t) = Se^{yT}N(d_1) - Ke^{-r\times\tau}N(d_2), \\ \\ P(S_t, t) = Ke^{-r\times\tau}(1 - N(d_2)) - Se^{y\times T}(1 - N(d_1)), \end{cases}$$

where:

$$\begin{cases} d_1 = \dfrac{\ln\left(\dfrac{S_t}{K}\right) + \tau\left(r + \dfrac{\sigma^2}{2}\right)}{\sigma\sqrt{\tau}} \\ d_2 = d_1 - \sigma\sqrt{\tau} \end{cases}$$

, further the Put Option price corresponds to the **Put-Call parity**, given by:

$$C(S_t, t) + Ke^{-r\times\tau} = P(S_t, t) + S_t$$

Note As here we don't have dividends, then $y = 0$, and so

$$\begin{cases} C(S_t, t) = S_t N(d_1) - Ke^{-r\times\tau}N(d_2), \\ \\ P(S_t, t) = Ke^{-r\times\tau}(1 - N(d_2)) - S_t(1 - N(d_1)), \end{cases}$$

BlackScholes function

The Black-Scholes function is implemented under `OptionPricing.R::black-scholes()`:

```
# Test: Call Option
S_t = 1540
K = 1600
r = 0.03
tau = 10/360
sigma = 1.05
black_scholes(S_t, K, r, tau, sigma)
```

```
## [1] 80.81672
```

Book of Options

Assume the following book of **European Call Options:**

1. **1x** strike $K = 1600$ with maturity $T = 20d$
2. **1x** strike $K = 1650$ with maturity $T = 20d$
3. **1x** strike $K = 1750$ with maturity $T = 40d$
4. **1x** strike $K = 1800$ with maturity $T = 40d$

Find the price of this book given **the last underlying price** and the **last implied volatility** (take the VIX for all options). Use **Black-Scholes** to price the options. Take the current term structure and **linearly interpolate** to find the corresponding rates. Use 360 days/year for the term structure and **250 days/year** for the maturity of the options.

We pack these into a list:

```
# Initialize strikes and maturities the options
T_vec <- c(20, 20, 40,40) #  maturities
K_vec <- c(1600, 1650, 1750, 1800) # Strikes
option_book <- list(T = T_vec, K = K_vec)
option_book
```

```
## $T
## [1] 20 20 40 40
##
## $K
## [1] 1600 1650 1750 1800
```

Nearest values

This function will obtain the two nearest values a, b for a number x in a vector v, such that $a < x < b$.

```
# Test: function used to get two nearest values in a vector (OptionsPricing.R)
days <- rf_mat[, "days"]
get_nearest(40, rf_mat[, "days"]) # nearest day values
```

```
## 1m 3m
## 30 90
```

Linear Interpolation

Given two known values (x_1, y_1) and (x_2, y_2), we can estimate the y-value for some x-value with:

$$y = y_1 + \frac{(x - x_1)(y_2 - y_1)}{(x_2 - x_1)}$$

This function `interpolate()` is implemented under the `OptionPricing.R` script.

Finding the rates through interpolation

The **yield curve** for the given structure of interest rates can be modeled a function $r_f = f(x)$,where x is the number of years. Then, we can interapolate the values from `rf_mat`. This is done in the `price_option()` function under `code/OptionPricing.R`

Example

1x strike $K = 1600$ with maturity $T = 20d$

```
S_t = sp500[length(sp500)] # last price of underlying
IV = vix[length(vix)] # last volatility

## test: specific price (func from OptionPricing.R)
price_option(T=20, K=1600, calls = calls, rf_mat =  rf_mat, stock = NA, S_t = S_t, IV = IV)
```

```
## $Call
## [1] 87.56885
##
## $Put
## [1] NA
##
## $S
## [1] 1683.99
##
## $K
## [1] 1600
##
## $r_interp
## [1] 0.001264335
##
## $calls
##         K        tau        IV  tau_days
## [1,] 1600 0.02557005 0.1817481  6.392513
## [2,] 1600 0.10228238 0.1701946 25.570595
##
## $rates
##              rf      years      days
## 1w 0.0009799908 0.01923077  6.923077
## 1m 0.0012799317 0.08333333 30.000000
```

where,

- `$Call`: The calculated Call option price
- `$Put`: The calculated Put option price (if `put=TRUE`. Set to `FALSE` by default).
- `$S`: Underlying price
- `$K`: Strike price
- `$r_intep`: Interpolated risk-free rate from the term structure of risk-free rates.
- `$calls`: Relevant values from the `calls` matrix.
- `$rates`: Rates used to find the interpolation.

Pricing the book of options

Next, using the function above we price the book of options given:

1. **1x** strike $K = 1600$ with maturity $T = 20d$
2. **1x** strike $K = 1650$ with maturity $T = 20d$
3. **1x** strike $K = 1750$ with maturity $T = 40d$
4. **1x** strike $K = 1800$ with maturity $T = 40d$

First, we retrieve the latest value for the underlying (SP500) and the latest implied volatility (VIX):

```
S_t = sp500[length(sp500)] # last price of underlying
IV = vix[length(vix)] # last volatility
```

Then, we price the options accordingly:

```
# First Call Option
price_option(T=20, K=1600, calls=calls, rf_mat=rf_mat, S_t = S_t, IV = IV)
```

```
## $Call
## [1] 87.56885

Some Theoretical Workings

We present some important theory from which we based the implementation of a variety of the functions we use in this project.

Log-returns

The **discrete returns** are given by:

$$R_{t+1} = \frac{P_{t+1} - P_t}{P_t}$$

and the next ahead log-returns are given by:

$$\log(R_{t+1}) = \log(P_{t+1} - P_t) - \log(P_t)$$

Since this is shared by all the subsequent parts, we compute the log-returns for both of the indexes.

```
# load required libraries
library("PerformanceAnalytics")

# calculate returns
sp500_rets <- PerformanceAnalytics::CalculateReturns(sp500, method="log")
vix_rets <- PerformanceAnalytics::CalculateReturns(vix, method="log")

# remove first return
sp500_rets <- sp500_rets[-1]
vix_rets <- vix_rets[-1]

# remove nas
sp500_rets[is.na(sp500_rets)] <- 0
vix_rets[is.na(vix_rets)] <- 0

# display
head(sp500_rets)
```

```
##                    sp500

```

Computing Prices from Returns

In order to produce forecasts, we crate a function to forecast the 5 day ahead prices from the returns. Since:

$$
\begin{aligned}
R_t &= \frac{P_t - P_{t-1}}{P_{t-1}} \\
\implies R_t &= \frac{P_t}{P_{t-1}} - 1 \\
\implies \log(R_t) &= \log\left(\frac{P_t}{P_{t-1}}\right) \\
\implies \log(R_t) &= \log(P_t) - \log(P_{t-1}) \\
\implies \log(P_t) &= \log(R_t) + \log(P_{t-1}) \\
\implies P_t &= \exp(\log(R_t) + \log(P_{t-1})) \\
\implies P_{t+1} &= \exp(\log(R_{t+1}) + \log(P_t))
\end{aligned}
$$

This logic is implemented in the `f_next_Pt()` and `f_logret_to_price()`, lkocated under the `code/Utils.R` folder.

Value at Risk (VaR) and Expected Shortfall (ES)

VaR: For a random variable X, the **Value-at-Risk (VaR)** at level α is defined as the α-lower quantile of the distribution of X, thus:

$$VaR_X(\alpha) = F_X^{-1}(1-\alpha)$$

ES: Expected shortfall is calculated by averaging all of the returns in the distribution that are worse than the VAR of the portfolio at a given level of confidence.

Profit of an European Option

The profit functions of a long call and a long put are given by:

$$
\begin{aligned}
\pi^{\text{Long Call}} &= \max(S_T - K, 0) - c \\
\pi^{\text{Long Put}} &= \max(K - S_T, 0) - p
\end{aligned}
$$

, where:

- S: Spot price (current)
- S_0: Spot price at the begining of the option
- S_T: Spot price at maturity
- T: Maturity of option
- K: Strike price
- c: Price of Call option
- p: Price of Put option

One risk driver and Gaussian Model

Steps:

1. Compute the daily log-returns of the underlying stock.
2. Assume they are iid normally distributed.
3. Generate 10 000 scenarios for the one-week ahead (five days) underlying price using the normal distribution fitted to the past invariants.
4. Determine the P&L distribution of the book of options, using the simulated underlying values. Assume the implied volatility stays the same. Take interpolated rates for the term structure.
5. Compute the VaR95 and the ES95.

Gaussian fit to underlying and simulation

```
# simulation parameters
n_ahead = 5  # number of days ahead
n_sim = 10000 # number of simulations

# Obtain MLE Gaussian parameters from the log-returns
mean_sp500 = mean(sp500_rets) #mean of sp500
sd_sp500 = sd(sp500_rets) #standard deviation of sp500

# examine parameters
mean_sp500
```

```
## [1] 0.00004283042
```

```
sd_sp500
```

```
## [1] 0.01332592
```

```
#initialize matrix of returns forecasted until T+5
sp500_rets_forecast = matrix(NA,n_sim, n_ahead)

# simulate for each day-ahead
for(t in 1:n_ahead)
{
  # sample 10k times from the Gaussian with MLE fitted parameters
  sp500_rets_forecast[, t] = rnorm(n_sim,
                                   mean = mean_sp500,
                                   sd = sd_sp500)
}

# assign column names to simulations
colnames(sp500_rets_forecast) = c("T+1", "T+2", "T+3", "T+4", "T+5")

# display
head(sp500_rets_forecast)
```

```
##                T+1           T+2          T+3          T+4          T+5

```

Pricing the simulations and Profit/Loss Distribution

Option Pricing of Simulated Values

Next, we calculate the price of the book of options for the simulated values using the `f_opt_price_simulation()` function under `code/OptionPricing.R`:

```
# random seed for replication
set.seed(123)

# obtain number of strike prices
n_K <- length(option_book$K)

# generate option names for the list
optnames <- as.vector(mapply(paste0, rep("opt", n_K), seq(1:n_K)))

# Initialize Profit/Loss mats for each option in the book
call_price_matrices <- initialize_sim_mats(sim_price_sp500_one_driver,# copy mat dims
                                            num_mats = length(K_vec),
                                            lnames=optnames
                                            )

# Initialize Profit/Loss mats for each option in the book
PL_matrices <- initialize_sim_mats(sim_price_sp500_one_driver,
                                   num_mats = length(K_vec),
                                   lnames=optnames
                                   )
```

```r
#Loop to calculate the P&L of each option from our book of options
for(i in 1:n_K) # each of the options
{
  for(j in 1:n_ahead) # for each of the days
  {
    # compute the call price for the i-th option at the j-th day
    price_call = prc_opt(option_book$T[i]-j, # shifted maturity
                         option_book$K[i], # strike price
                         calls, # matrix of calls values
                         rf_mat, # structure of risk-free rates
                         sim_price_sp500_one_driver[,j],
                         vix[[length(vix)]]) # use the last day of the vix for all options prices

    # Assign the Call price to matrix
    call_price_matrices[[i]][,j] = price_call

    # Compute and assign profit loss for opt i at  day j
    PL_matrices[[i]][,j] = option_profit(S = sim_price_sp500_one_driver[,j],
                                         K = option_book$K[i],
                                         c = price_call)$call_profit

  }
}
```

VaR and ES

In what follows, we compute the 95% VaR and 95% ES for the P/L for the book of options (drawn as a red and black vertical lines in the previous plots).

95% VaR

```
opt1_one_driver_VaR_ES$VaR # first option
```

```
## [1] 67.38727
```

```
opt2_one_driver_VaR_ES$VaR # second option
```

```
## [1] 62.15181
```

```
opt3_one_driver_VaR_ES$VaR # third option
```

```
## [1] 4.69026
```

```
opt4_one_driver_VaR_ES$VaR # fourth option
```

```
## [1] -9.507812
```

95% ES

```
opt1_one_driver_VaR_ES$ES # first option
```

```
## [1] 54.07015
```

```
opt2_one_driver_VaR_ES$ES # second option
```

```
## [1] 50.34775
```

```
opt3_one_driver_VaR_ES$ES # third option
```

```
## [1] -0.3716741
```

```
opt4_one_driver_VaR_ES$ES # fourth option
```

```
## [1] -12.98313
```

Two risk drivers and Gaussian Model

1. Compute the daily log-returns of the underlying stock.
2. Compute the daily log-returns of the VIX.
3. Assume they are invariants normally distributed.
4. Generate 10 000 scenarios for the one-week ahead underlying price and the one week ahead VIX value using the normal distribution fitted to the past risk drivers.
5. Determine the P&L distribution of the book of options, using the simulated values. Take interpolated rates for the term structure.

Multivariate Gaussian Distribution

A random vector with a multivariate Gaussian dsitribution has pdf given by:

$$f(x) = \frac{1}{(2\pi)^{d/2}|\Sigma|^{-1}} \exp\left(-\frac{1}{2}(x-\mu)^T\Sigma^{-1}(x-\mu)\right),$$

where the mean vector μ and covariance matrix Σ are given by:

$$\mu := \mathbb{E}[X] \quad , \quad \Sigma := Cov(X) = \mathbb{E}[(X-\mu)(X-\mu)^T],$$

Generating the simulation scenarios

```
# random seed for replication
set.seed(1234)

# Simulation parameters
n_sim = 10000 # set number of simulations
n_ahead = 5 # days ahead to produce samples

# MLE parameters to fit Bivariate Gaussian
rets <- rets <- cbind(sp500_rets, vix_rets)
mu <- apply(rets, 2, mean)
Sigma <- cov(rets)

# preallocate matrices to store simulations
sim_rets_sp500_two_drivers <- matrix(NA, nrow = n_sim, ncol=n_ahead)
sim_rets_vix_two_drivers <- matrix(NA, nrow = n_sim, ncol=n_ahead)

# assign days ahead
colnames(sim_rets_sp500_two_drivers) <- c("T+1", "T+2", "T+3", "T+4", "T+5")
colnames(sim_rets_vix_two_drivers) <- c("T+1", "T+2", "T+3", "T+4", "T+5")

# perfom n_ahead days of n_sim scenarios
for(t in 1:n_ahead){

  # Sample n_sim times from Bivariate Gaussian
  U_sim <- rmvnorm(mean = mu, sigma = Sigma, n = n_sim)

  # store simulation of log return in matrix
  sim_rets_sp500_two_drivers[ ,t] <- U_sim[, 1]
  sim_rets_vix_two_drivers[ ,t] <- U_sim[, 2]
}

# preview of simulated log returns
head(sim_rets_sp500_two_drivers)
```

```

```

Pricing the simulation scenarios

Recall the initial (call) options:

1. **1x** strike $K = 1600$ with maturity $T = 20d$
2. **1x** strike $K = 1650$ with maturity $T = 20d$
3. **1x** strike $K = 1750$ with maturity $T = 40d$
4. **1x** strike $K = 1800$ with maturity $T = 40d$

Option Pricing of Simulated Values

Next, we calculate the price of the book of options for the simulated values using the `f_opt_price_simulation()` function under `code/OptionPricing.R`:

```
# random seed for replication
set.seed(123)

# Obtain the obtion prices from simulation values
opt_price_mats_two_drivers <- f_opt_price_simulation(sim_price_sp500 = sim_price_sp500_two_drivers,
                                                     sim_vol_vix = sim_vol_vix_two_drivers,
                                                     K_vec = option_book$K,
                                                     T_vec = option_book$T,
                                                     put=FALSE)
```

```
# overview of dataframes
head(opt_price_mats_two_drivers$opt1)
```

```

```

Two risk drivers and copula-marginal model (Student-t and Gaussian Copula)

1. Compute the daily log-returns of the underlying stock
2. Assume the first invariant is generated using a Student-t distribution with $\nu = 10$ df and the second invariant is generated using a Student-t distribution with $\nu = 5$ df.
3. Assume the **normal copula** to merge the marginals.
4. Generate 10000 scenarios for the one-week ahead price for the underlying and the one-week ahead VIX value using the copula.
5. Determine the P&L distribution of the book of options, using the simulated values.
6. Take interpolated rates for the term structure.

Gaussian Copula with two Student-t marginals

A bivariate distribution H can be formed via a copula C from two marginal distributions with CDFs F and G via:

$$H(x, y) = C(F(x), G(y)) = C(F^{-1}(u), G^{-1}(u))$$

with density

$$h(x, y) = c(F(x), G(y))f(x)g(y)$$

The **Gaussian Copula** is given by:

$$C_\rho^{\text{Gauss}}(u, v) = \Phi_\rho(\Phi^{-1}(u), \Phi^{-1}(v)).$$

In this case, a Gaussian copula with two Student-t marginals with CDFs $t(\nu_1)$ with ν_1 degrees of freedom and $t(\nu_2)$ with ν_2 degrees of freedom is given by:

$$C_\rho^{\text{Gauss}}(u, v) = \Phi_\rho(F_{\nu_1}^{-1}(u), F_{\nu_1}^{-1}(v)),$$

where F_{ν_1} and F_{ν_2} are their respective CDFs.

Generating the simulation scenarios

Assumptions: - Marginal Student-t distributions - Disregard time dependence in the bootstrapping process

```
# random seed for replication
set.seed(123)

# convert to vector since fitting without dependence
sp500_rets_vec <- as.vector(sp500_rets)
vix_rets_vec <- as.vector(vix_rets)

# calculate means and sds for both indices
mu <- c(mean(sp500_rets_vec), mean(vix_rets_vec))
sigma <- c(sd(sp500_rets_vec), sd(vix_rets_vec))

# display
mu
```

```
## [1]  0.00004283042 -0.00014976541
```

```
sigma
```

```
## [1] 0.01332592 0.06367330
```

Fitting Student-t to the marginals

```
## Fit marginals by MLE

# Student-t for sp500
fit1 <- suppressWarnings(
  fitdistr(x = sp500_rets_vec,
           densfun = dstd,
           start = list(mean = 0, sd = 1, nu = 10))
  )
theta1 <- fit1$estimate #extract fitted parameters

# Student-t for vix
fit2 <- suppressWarnings(
  fitdistr(x = vix_rets_vec,
           densfun = dstd,
           start = list(mean = 0, sd = 1, nu = 5))
  )
theta2 <- fit2$estimate # extract fitted parameters

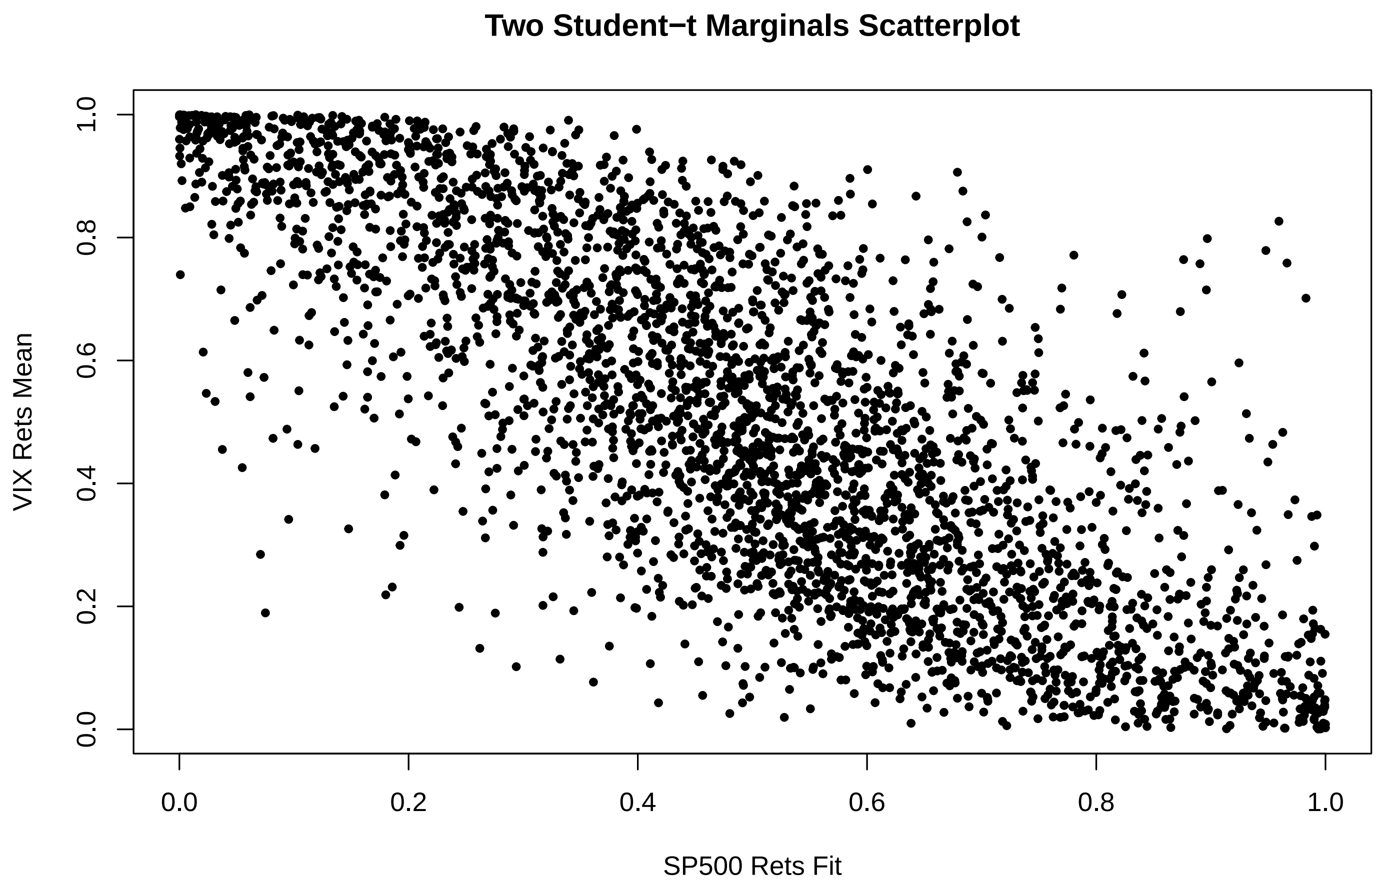
# display parameters
theta1
```

```
##         mean           sd           nu
## 0.0004414879 0.0156603739 2.6953920404
```

```
theta2
```

```
##         mean           sd           nu
## -0.003475206  0.064192681  4.230323432
```

```
# Fit Student-t to the marginals
U1 <- pstd(sp500_rets_vec, mean = theta1[1], sd = theta1[2], nu = 10) # sp500
U2 <- pstd(vix_rets_vec,mean = theta2[1], sd = theta2[2], nu = 5) # vix
U <- cbind(U1, U2) # join into one matrix
plot(U, pch = 20, cex = 0.9, main= "Two Student-t Marginals Scatterplot", xlab="SP500 Rets Fit", ylab="VIX Ret
```



Fitting the copula

```r
# Obtain the best rho for the Gaussian Copula
C <- copula::normalCopula(dim = 2)
fit <- copula::fitCopula(C, data = U, method = "ml")
fit
```

```
## Call: copula::fitCopula(C, data = U, ... = pairlist(method = "ml"))
## Fit based on "maximum likelihood" and 3409 2-dimensional observations.
## Copula: normalCopula
##   rho.1
## -0.7984
## The maximized loglikelihood is 1494
## Optimization converged
```

Sampling from the copula

```r
## TEST: Sampling from copula n_sim times for one day

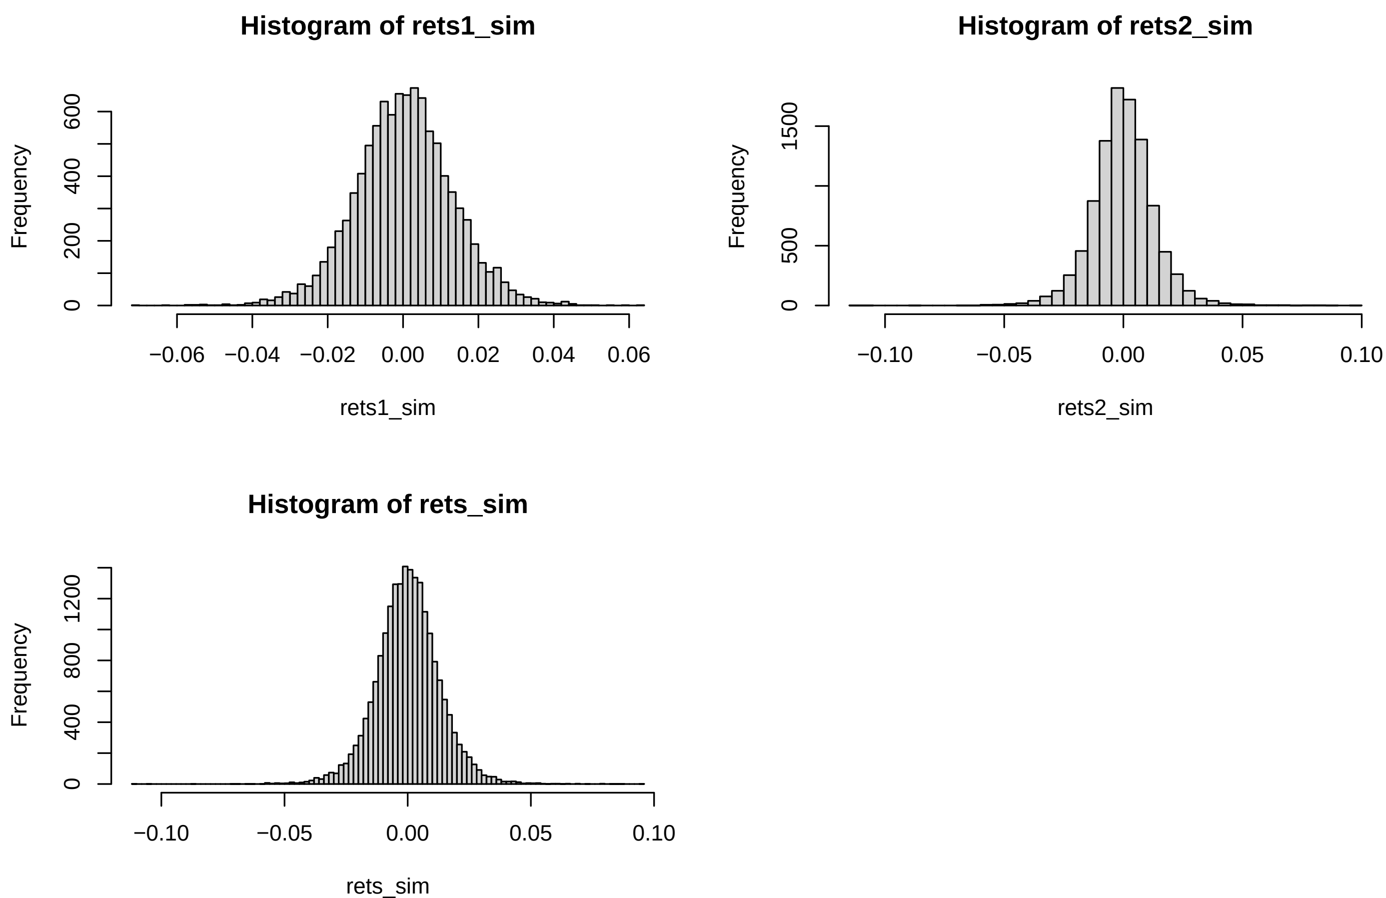
# seed for replication
set.seed(420)

# Simulation parameters
n_sim = 10000 # set number of simulations
```

```r
# produce simulations from copula
U_sim <- rCopula(n_sim, fit@copula)

# use copula U_sim to reproduce the marginals with student-t distr
rets1_sim <- qstd(U_sim[,1], mean = mu[1], sd = sigma[1], nu = 10) # sp500
rets2_sim <- qstd(U_sim[,2], mean = mu[1], sd = sigma[1], nu = 5) # vix
rets_sim <- cbind(rets1_sim, rets2_sim)

# visualize
par(mfrow = c(2,2))
hist(rets1_sim, nclass=50)
hist(rets2_sim, nclass=50)
hist(rets_sim, nclass = round(10 * log(n_sim)))
```



We can now sample for the five days of interest using the fitted copula with marginal Student-t for the invariants:

```r
# random seed for replication
set.seed(69)

##############################
### Setup & Initialization ###
##############################

# Simulation parameters
n_sim = 10000 # set number of simulations
n_ahead = 5 # days ahead to produce samples

# preallocate matrices to store simulations
sim_rets_sp500_copula <- matrix(NA, nrow = n_sim, ncol=5)
```

```r
sim_rets_vix_copula <- matrix(NA, nrow = n_sim, ncol=5)

# assign days ahead
colnames(sim_rets_sp500_copula) <- c("T+1", "T+2", "T+3", "T+4", "T+5")
colnames(sim_rets_vix_copula) <- c("T+1", "T+2", "T+3", "T+4", "T+5")

##############################
### Running the simulation ###
##############################

# perform n_head days of n_sim scenarios
for(t in 1:n_ahead){

  # Sample n_sim times from Gaussian Copula
  U_sim <- rCopula(n_sim, fit@copula)

  # use copula U_sim to reproduce the marginals quantiles F^{-1}(u) with student-t distr
  rets1_sim <- qstd(U_sim[,1], mean = theta1[1], sd = theta1[2], nu = 10) # sp500
  rets2_sim <- qstd(U_sim[,2], mean = theta2[1], sd = theta2[2], nu = 5) # vix
  # rets1_sim <- qt(U_sim[,1], df = 10) # sp500
  # rets2_sim <- qt(U_sim[,2], df = 5) # vix

```

Pricing the simulation scenarios

Recall the initial (call) options:

1. **1x** strike $K = 1600$ with maturity $T = 20d$
2. **1x** strike $K = 1605$ with maturity $T = 40d$
3. **1x** strike $K = 1800$ with maturity $T = 40d$

Option Pricing of Simulated Values

Next, we calculate the price of the book of options for the simulated values using the `f_opt_price_simulation()` function under `code/OptionPricing.R`:

```
# random seed for replication
set.seed(123)

# Obtain the obtion prices from simulation values
opt_price_mats_copula <- f_opt_price_simulation(sim_price_sp500 = sim_price_sp500_copula,
                                                sim_vol_vix = sim_vol_vix_copula,
                                                K_vec = option_book$K,

Distribution of the Profit and Loss for the Book Of Options

Calculating the profits

For each of the simulated prices and resulting premiums, we want to calculate the profit generated at each simulation timestep. The function used is `f_pl_simulation()`, found under `code/OptionPricing.R`.

```
# Compute the profits and loses for the simulation  from the simulated option premiums
PL_mats_copula <- f_pl_simulation(sim_price_sp500 = sim_price_sp500_copula,
                                  opt_price_mats = opt_price_mats_copula,
                                  K_vec = option_book$K)
```

```
# display profit matrices
head(PL_mats_copula$PL1)
```

```

Distribution of Options P/L

Next, using all the simulated profits and losses for each of the options, we display a histogram for the distribution for each of the options, for the aggregated 5 days of simulation:

```
# flatten the matrices 5-days ahead simulated P/L for the three options
sim_pl_opt1_copula <- as.vector(PL_mats_copula$PL1)
sim_pl_opt2_copula <- as.vector(PL_mats_copula$PL2)
sim_pl_opt3_copula <- as.vector(PL_mats_copula$PL3)
sim_pl_opt4_copula <- as.vector(PL_mats_copula$PL4)

# Compute the 95% VaR and 95% ES
opt1_copula_VaR_ES <- f_VaR_ES(sim_pl_opt1_copula, alpha = 0.05)
opt2_copula_VaR_ES <- f_VaR_ES(sim_pl_opt2_copula, alpha = 0.05)
opt3_copula_VaR_ES <- f_VaR_ES(sim_pl_opt3_copula, alpha = 0.05)
opt4_copula_VaR_ES <- f_VaR_ES(sim_pl_opt4_copula, alpha = 0.05)

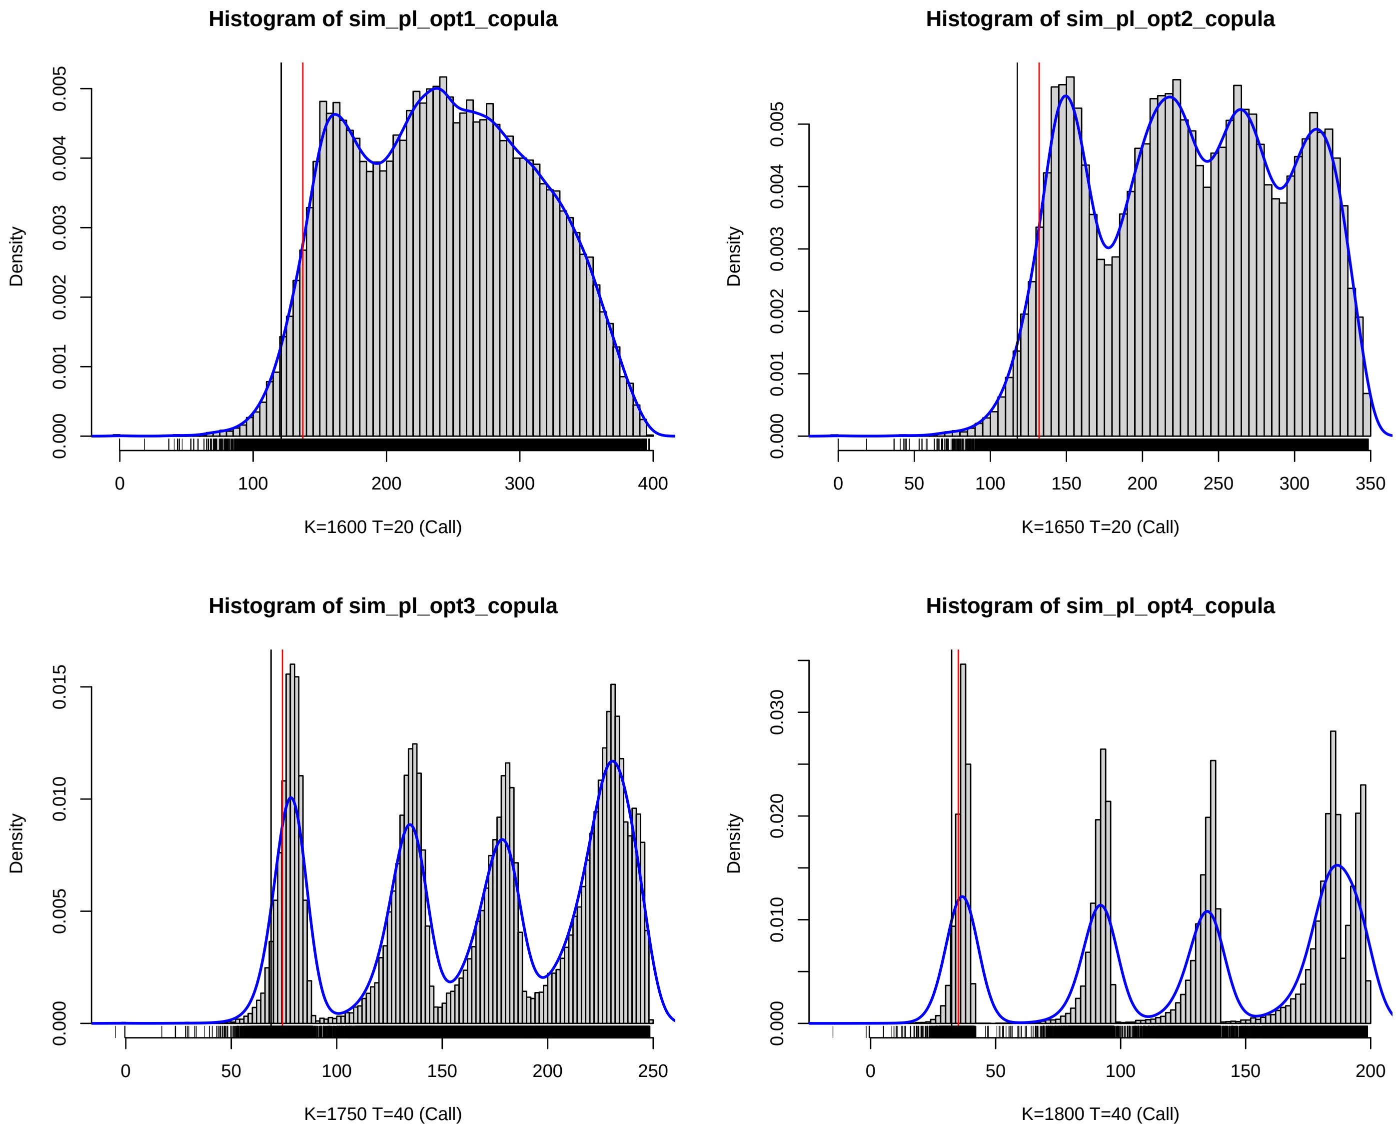
# plotting grid
par(mfrow = c(2,2))

# plot the distribution for each of the options
hist(sim_pl_opt1_copula, nclass = round(10 * log(n_sim)),
     probability = TRUE, xlab=paste0("K=", K_vec[1], " T=", T_vec[1], " (Call)"))
lines(density(sim_pl_opt1_copula), lwd=2, col="blue")
abline(v=opt1_copula_VaR_ES$VaR, col="red") # 95% VaR
abline(v=opt1_copula_VaR_ES$ES, col="black") # expected shortfall
rug(sim_pl_opt1_copula)

# plot the distribution for each of the options
hist(sim_pl_opt2_copula, nclass = round(10 * log(n_sim)),
     probability = TRUE, xlab=paste0("K=", K_vec[2], " T=", T_vec[2], " (Call)"))
lines(density(sim_pl_opt2_copula), lwd=2, col="blue")
abline(v=opt2_copula_VaR_ES$VaR, col="red") # 95% VaR
abline(v=opt2_copula_VaR_ES$ES, col="black") # expected shortfall
rug(sim_pl_opt2_copula)

# plot the distribution for each of the options
hist(sim_pl_opt3_copula, nclass = round(10 * log(n_sim)),
     probability = TRUE, xlab=paste0("K=", K_vec[3], " T=", T_vec[3], " (Call)"))
lines(density(sim_pl_opt3_copula), lwd=2, col="blue")
abline(v=opt3_copula_VaR_ES$VaR, col="red") # 95% VaR
abline(v=opt3_copula_VaR_ES$ES, col="black") # expected shortfall
rug(sim_pl_opt3_copula)

# plot the distribution for each of the options
hist(sim_pl_opt4_copula, nclass = round(10 * log(n_sim)),
     probability = TRUE, xlab=paste0("K=", K_vec[4], " T=", T_vec[4], " (Call)"))
lines(density(sim_pl_opt4_copula), lwd=2, col="blue")
abline(v=opt4_copula_VaR_ES$VaR, col="red") # 95% VaR
abline(v=opt4_copula_VaR_ES$ES, col="black") # expected shortfall
rug(sim_pl_opt4_copula)
```



These all look like multimodal distributions. The last one, particularly shows a different mode for each of the fives days computed. The 95% VaR (red) and ES (black) are all displayed in the plots.

Volatility Surface

Steps:

1.Fit a volatility surface to the implied volatilities observed on the market (traded call and put options).Minimize the absolute distance between the market implied volatilities and the model implied volatilities. The parametric surface is given by:

$$\sigma(m,\tau) = \alpha_1 + \alpha_2(m-1)^2 + \alpha_3(m-1)^3 + \alpha_4\sqrt{\tau},$$

where: - $m = K/S$ is the **monyness**. - τ is the time to maturity of the option in years. - $\alpha_1, \ldots, \alpha_4$ are model parameters.

2. Re-price the portfolio in one week assuming the same parametric model but shifted by the one-year ATM implied volatility difference.

Note: ATM means at-the-money, which means that $m = 1$. Assume that the one-year ATM implied volatility given by the VIX is $(\alpha_1 + \alpha_4)$.

Traded Options data

First, we do some data preparation with the traded options available. Since for $K > S$ a put option has zero profit (don't want to exercise at a higher price), we discard values with $m > 1$, and similarly for call options with $m < 1$.

```
#initialize the last price of the underlying
S <- Market$sp500[length(Market$sp500)][[1]] #3410
VIX <- as.numeric(Market$vix[length(Market$vix)])

# convert to draframe for easier manipulation
calls_df <- as.data.frame(calls)
puts_df <- as.data.frame(puts)

# assign extra column to puts (1) and calls (0)
calls_df["type"] <- "call"
puts_df["type"] <- "put"

# check dimensions
dim(calls_df)
```

```
## [1] 422   5
```

```
dim(puts_df)
```

```
## [1] 750   5
```

```
# stack both of these matrices together
puts_calls <- rbind(calls_df, puts_df)

# integrate the price
puts_calls["S"] <- rep(S, nrow(puts_calls))
puts_calls["m"] <- puts_calls["K"]/puts_calls["S"]

# filter the calls that have moniness over one
calls_m_over <- puts_calls[(puts_calls["type"] == "call") & (puts_calls["m"] >= 1), ]

# filter the puts that have moniness below one
puts_m_under <- puts_calls[(puts_calls["type"] == "put") & (puts_calls["m"] < 1), ]

# combine these results into putcalls again
call_put_data <- rbind(calls_m_over, puts_m_under)
```

```
head(call_put_data)
```

```

Fitting the volatility surface

The functions that we will use are implemented under `code/VolatilitySurface.R`. The optimization problem can be written as:

$$
\begin{aligned}
\vec{\alpha}^* &= \arg\min_{\vec{\alpha}} \sum_{t=1}^{T} \left|\sigma_t^{observed} - \sigma(m.\tau)\right| \\
&= \arg\min_{\alpha_1,\alpha_2,\alpha_3,\alpha_4} \sum_{t=1}^{T} \left|\sigma_t^{observed} - \left(\alpha_1 + \alpha_2(m-1)^2 + \alpha_3(m-1)^3 + \alpha_4\sqrt{\tau}\right)\right|
\end{aligned}
$$

```
# Optimize the objective using available data
alpha <- f_sig_optim(call_put_data)
alpha # best fitted parameters
```

```
## [1]  0.21914594  1.69482614  1.33353414 -0.07907473
```

Volatility Surface Plot

```
#Summary of data
Moneyness <- call_put_data$m
Tau <- call_put_data$tau

#Initialize x and y axis
maturity <- seq(from =0, to = 2.5, by = 0.05)
moneyness <-  seq(from =0, to = 2, by = 0.05)

# memory allocation
IV <- matrix(NA, nrow = length(moneyness), ncol = length(maturity))

# Creating (x,y,z) values for the surface
for(i in 1:length(moneyness)){
  for(j in 1:length(maturity)){
    IV[i,j] <- f_sig_IV(alpha, moneyness[i], maturity[j])
```

```
  }
}

# perspective plot
persp(x = moneyness, y = maturity, z = IV,
      xlab = "m",
      ylab = "tau",
      zlab = "IV",
      main = "Fitted Volatility Surface",
      ylim = c(0,2.5), xlim = c(0, 2), zlim = c(0,8),
      theta = 30, phi = 30, expand = 0.5,

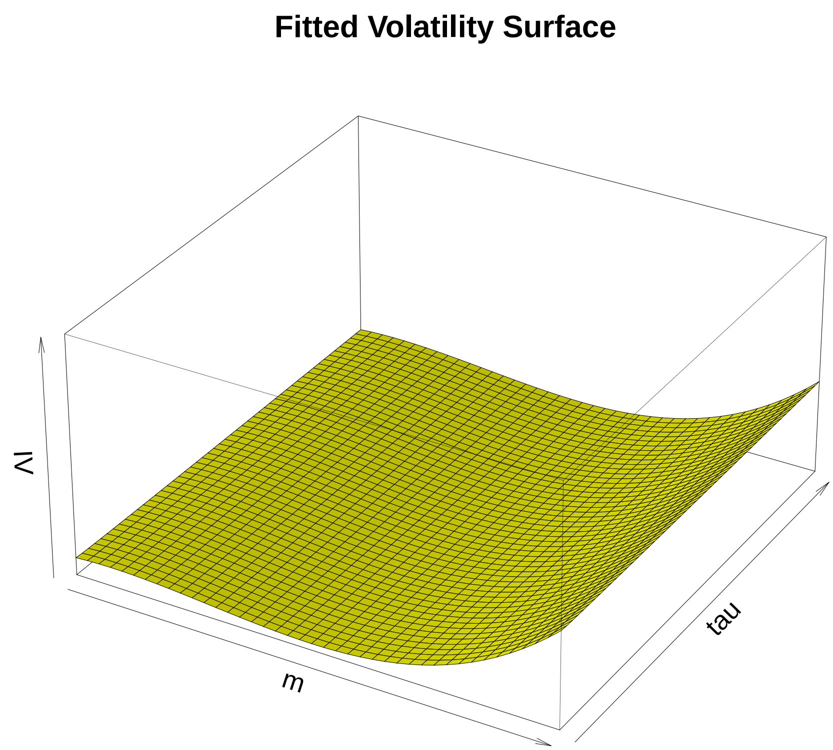
      tck = 1, r = 15, d = 0.5
      )
```



re-pricing the Portfolio with

Full Approach

1. Filter the volatility clustering of the log-returns of the underlying using a GARCH(1,1) model with Normal innovations. Use the residuals as invariants.
2. Take and AR(1) model for the log-returns of the VIX. Use the residuals as invariants.
3. Use normal marginals for the invariants and a normal copula.
4. Generate draws for the invariants, compute next week (five days) values and reprice the portfolio.
5. Compute the VaR95 and ES95.

Log returns of the underlying

```
# load reqruired libraries
library("PerformanceAnalytics")

# calculate returns
sp500_rets <- PerformanceAnalytics::CalculateReturns(sp500, method="log")
vix_rets <- PerformanceAnalytics::CalculateReturns(vix, method="log")

# remove first return
sp500_rets <- sp500_rets[-1]
vix_rets <- vix_rets[-1]

# remove nas
sp500_rets[is.na(sp500_rets)] <- 0
vix_rets[is.na(vix_rets)] <- 0

# display
head(sp500_rets)
```

\begin{aligned}
\mathbb{E}[Y_t] &\approx 0 \\
\mathbb{V}ar[Y_t] = \mathbb{E}[\epsilon_t^2] = \mathbb{E}[\sigma_t^2] &= \frac{\omega}{(1-\alpha-\beta)}
\end{aligned}
$$

Stationarity Conditions

$$
\begin{aligned}
\omega &\geq 0 \\
\alpha\ ,\ \beta &> 0 \\
\alpha + \beta &< 1 \quad \text{(Covariance-Stationary)}
\end{aligned}
$$

VaR

$$
VaR_Y(\alpha) = \Phi^{-1}(1-\gamma)\sigma_t,
$$

Log-likelihood

$$
\ln L(\theta|\mathbf{y}) = -\frac{T}{2}\ln(2\pi) - \sum_{t=1}^{T}\ln\sigma_t^2 - \frac{1}{2}\sum_{t=1}^{T}\frac{y_t^2}{\sigma_t^2}.
$$

Volatility clustering of the log-returns of the underlying with GARCH(1,1)

Which indicates a high level of autocorrelation in the returns.

Fitting the GARCH(1,1)

```r
# source code for garch
source(here("code", "GARCH.R")) # GARCH model implementation

# Estimate the GARCH(1,1) model
fit_garch <- f_optim_garch(sp500_rets)
```

```r
## Aside: If we had used the MSGARCH package

# load MSGARCH
library("MSGARCH")
# GARCH with NOrmal innovations
garch_n <- MSGARCH::CreateSpec(variance.spec = list(model = c("sGARCH")),
                               distribution.spec = list(distribution = c("norm")))
fit_garch_n <- MSGARCH::FitML(spec = garch_n, data = sp500_rets)

#check the fit
summary(fit_garch_n)
```

```

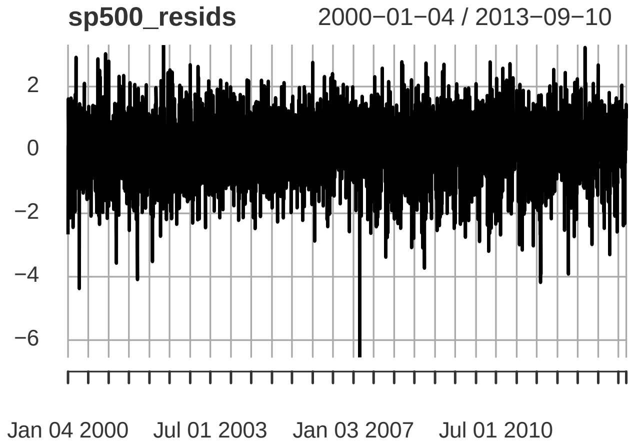
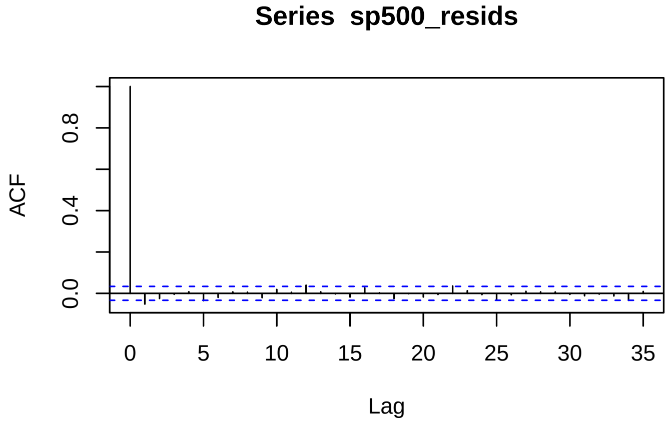
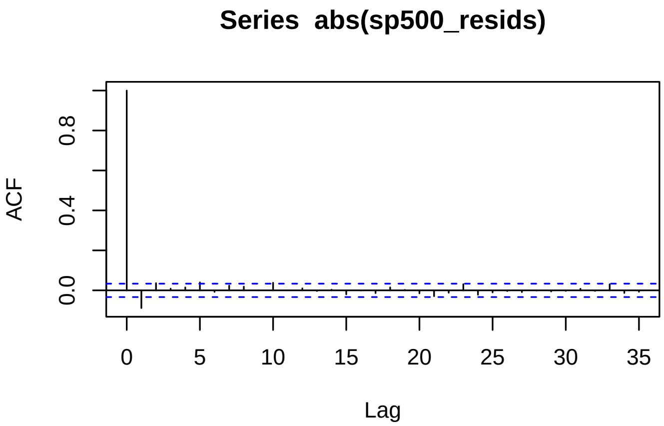
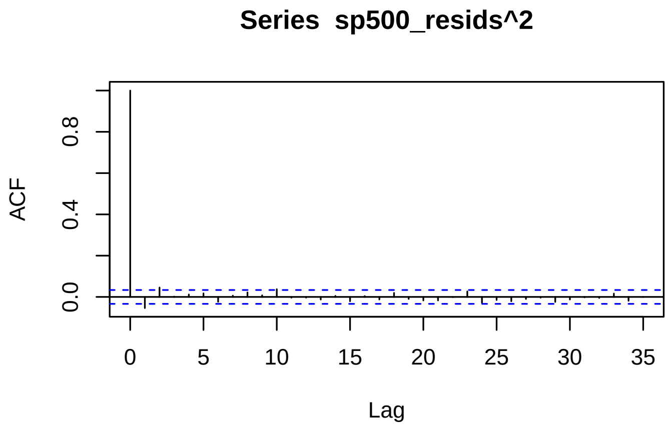
# autocorr of the variance of the innovations
acf(sp500_resids^2)
```









Fitting GARCH(1,1) with mean

AR(1) for the log-returns of the VIX

First-order Autoregressive Process AR(1)

- Let $\{\varepsilon_t\}$ be a mean-zero white noise process with variance σ^2.
- Consider a process $\{X_t\}$, independent of $\{\varepsilon_t\}$.
- Let ϕ be constant.

The **AR(1) process** satisfies:

$$X_t = \phi X_{t-1} + \varepsilon_t$$

It can be shown that:

$$\mu_X(t) = \mathbb{E}[X_t] = \phi \mu_X(t-1) = 0 \quad ,\forall t$$

when the process is stationary, and the autocovariance function $\gamma_X(h)$ with alg h and autocorrelation $\rho_X(h)$ are given by

$$\gamma_X(h) = \frac{\phi^{|h|}\sigma^2}{1-\phi^2} \quad \text{and} \quad \rho_X(h) = \phi^{|h|}$$

VIX log-returns

```r
library("forecast")

```

Normal Copula with Normal Marginals for the Invariants

Bivariate Gaussian Copula

Recall that the bivariate Gaussian copula is given by:

$$C_\rho^{\text{Gauss}}(u,v) = \Phi_\rho(\Phi^{-1}(u), \Phi^{-1}(v)). \quad \Longleftarrow \quad H(x,y) = C(F(x), G(y))$$

$$C_\rho^{\text{Gauss}}(u,v) = \int_{-\infty}^{\Phi^{-1}(u)} \int_{-\infty}^{\Phi^{-1}(v)} \frac{1}{2\pi\sqrt{1-\rho^2}} \exp\left(-\frac{x^2 - 2\rho xy + y^2}{2(1-\rho^2)}\right) dxdy$$

Gaussian marginals to the invariants

```
# invariants are the residuals
sp500_resids <- as.vector(sp500_resids)
vix_resids <- as.vector(vix_resids)

# display some values
head(sp500_resids, 10)
```

```

Transforming back the invariants to returns

From GARCH(1,1) residuals to SP500 returns

$$\hat{\epsilon}_t = \frac{y_t}{\hat{\sigma}_t} \implies \hat{y}_t = \hat{\epsilon}_t \hat{\sigma}_t$$

and

$$\begin{cases} \sigma_t^2 = \omega \ + \ \alpha y_{t-1}^2 + \beta \sigma_{t-1}^2 \\ \hat{y}_t = \hat{\epsilon}_t \hat{\sigma}_t \end{cases}$$

$$\begin{cases} \sigma_{T+1}^2 = \omega \ + \ \alpha y_T^2 + \beta \sigma_T^2 \\ \hat{y_{T+1}} = \hat{\epsilon}_{T+1} \hat{\sigma}_{T+1} \\ \vdots \\ \sigma_{T+t}^2 = \omega \ + \ \alpha y_{T+t-1}^2 + \beta \sigma_{T+t-1}^2 \\ \hat{y_{T+t}} = \hat{\epsilon}_{T+t} \cdot \hat{\sigma}_{T+t} \end{cases}$$

First, obtain last conditional variance available (up to time T):

```r
# load source code with GARCh custom functions
source(here("code", "GARCH.R")) # display the pdf through a 3-d chart

# data from up to T
y <- sp500_rets_vec
sig2 <- fit_garch$sig2_hat # vector of sig2 from GARCH
theta <- fit_garch$theta_hat # GARCH parameters

# initial parameters
y_prev <- y[length(y)] # last sp500 observation
sig2_prev <- sig2[length(sig2)] # last sig2_T

# residuals forecasted from copula (invariants)
garch_resids_next <- sim_inv_sp500
resids_next <- garch_resids_next[1, ] # example vector of residuals for prediction

# obtain 5days-ahead prediction for variance
sig2_forecast <- f_forecast_y(theta = theta,
                              sig2_prev = sig2_prev,
                              y_prev = y_prev,
                              resids_next = resids_next)

sig2_forecast
```

```
## $resids_next
##         T+1         T+2         T+3         T+4         T+5
##  0.04447154  1.56915167  1.39371665 -1.48356435  0.95655596
##

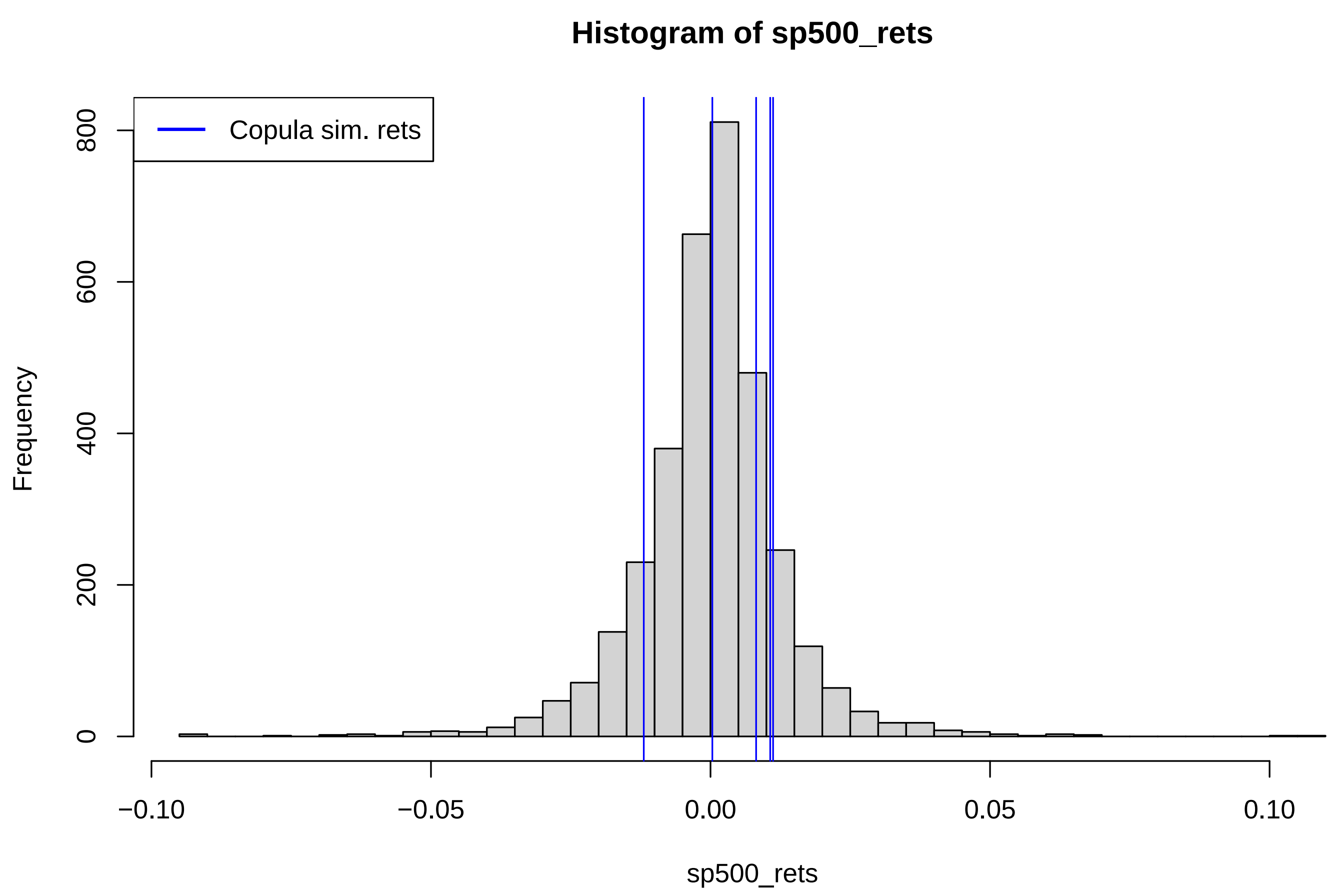
       lwd=rep(2, time=2))
```



From AR(1) residuals to VIX observations

The AR(1) model specifies

$$X_t = \phi X_{t-1} + \varepsilon_t$$

therefore for the step ahead predictions

$$
\begin{cases}
x_{T+1} = \phi x_T + \varepsilon_T \\
x_{T+2} = \phi x_{T+1} + \varepsilon_{T+1} \\
\vdots \\
x_{T+t} = \phi x_{T+t-1} + \varepsilon_{T+t-1}
\end{cases}
$$

Transforming the simulated returns into SP500 prices and VIX values

```
# data from up to T (VIX)
x <- vix_rets_vec

# initial parameters
phi <- vix_ar1$ar
x_prev <- x[length(x)] # last vix observation

# residuals forecasted from copula (vix invariants)
ar1_resids_next <- sim_inv_vix
ar1_res_next <- ar1_resids_next[1, ] # example vector

# forecast the vix values using the copula simulated residuals
ex_vix_forecast <- f_forecast_x(phi=phi, x_prev = x_prev, resids_next = ar1_res_next)
ex_vix_forecast
```

```

Pricing the simulation scenarios

Recall the initial (call) options:

1. **1x** strike $K = 1600$ with maturity $T = 20d$
2. **1x** strike $K = 1650$ with maturity $T = 20d$
3. **1x** strike $K = 1750$ with maturity $T = 40d$
4. **1x** strike $K = 1800$ with maturity $T = 40d$

Option Pricing of Simulated Values

Same as before, we calculate the price of the book of options for the simulated values using the `f_opt_price_simulation()` function under `code/OptionPricing.R`:

```
# random seed for replication
set.seed(123)

# Initialize strikes and maturities the options
T_vec <- c(20, 20, 40,40) #  maturities
K_vec <- c(1600, 1650, 1750, 1800) # Strikes

# Obtain the obtion prices from simulation values
opt_price_mats_full <- f_opt_price_simulation(sim_price_sp500 = sp500_sim_price_full,
                                              sim_vol_vix = vix_sim_vol_full,
                                              K_vec = K_vec,
                                              T_vec = T_vec,
                                              put=FALSE)
```

```
# overview of dataframes
head(opt_price_mats_full$opt1)
```

```

Distribution of the Profit and Loss for the Book Of Options

Calculating the profits

For each of the simulated prices and resulting premiums, we want to calculate the profit generated at each simulation timestep. The function used is `f_pl_simulation()`, found under `code/OptionPricing.R`.

```
# Initialize strikes and maturities the options
T_vec <- c(20, 20, 40,40) #  maturities
K_vec <- c(1600, 1650, 1750, 1800) # Strikes

# Compute the profits and loses for the simulation  from the simulated option premiums
PL_mats_full <- f_pl_simulation(sim_price_sp500 = sp500_sim_price_full,
                               opt_price_mats = opt_price_mats_full,
                               K_vec = K_vec)
```

```
# display profit matrices
head(PL_mats_full$PL1)
```

```
##          T+1      T+2       T+3      T+4      T+5
